GoogleTest

Pieter F

This page explains how to install the Google Test framework on Ubuntu.

Install dependencies and tools

First, install GCC, CMake, GNU Make and Git if you haven't already.

```
$ sudo apt update
$ sudo apt install gcc g++ cmake make git
```

Download, build and install

```
#!/usr/bin/env bash

#script to download and install GoogleTest

set -ex

version="release-1.10.0" # Release tag on GitHub
prefix="$HOME/.local"

cd /tmp

# Download
git clone --single-branch --depth=1 --branch "$version" \
https://github.com/google/googletest.git
mkdir googletest/build && cd $_
# Configure
cmake .. -DCMAKE_INSTALL_PREFIX="$prefix" -DCMAKE_BUILD_TYPE=Release
# Build
make -j$(nproc)
# Install
make install
```

Usage

To use GoogleTest in your project, you can use the following $CMake\ snippet$:

```
enable_testing()
find_package(GTest REQUIRED)
include(GoogleTest)

add_executable(test-exe test.cpp) # test.cpp contains TEST(...) cases
target_link_libraries(test-exe PRIVATE GTest::gtest_main)

if(NOT CMAKE_CROSSCOMPILING)
gtest_discover_tests(test-exe)
endif()
```

CMake has to find GoogleTest, so you need to make sure that \$HOME/.local is in its search paths. See Installing Locally.

Tested on

• Ubuntu 19.10 - GoogleTest 1.10.0
